Frequently Asked Questions

What is the main difference between prokaryotic and eukaryotic cells in Campbell Biology?

The main difference is that prokaryotic cells lack a true nucleus and other membrane-bound organelles, whereas eukaryotic cells have a true nucleus and other membrane-bound organelles.

How do photosynthetic organisms produce glucose according to Campbell Biology?

Photosynthetic organisms produce glucose through the process of photosynthesis, which involves the conversion of light energy from the sun into chemical energy stored in glucose molecules.

What is the role of mitosis in cell division as explained in Campbell Biology?

Mitosis is the process of cell division that results in two daughter cells with the same number of chromosomes as the parent cell, and it plays a crucial role in growth, repair, and maintenance of tissues.

What is the concept of natural selection in Campbell Biology?

Natural selection is the process by which populations of organisms adapt and evolve over time in response to environmental pressures, leading to the survival and reproduction of individuals with favorable traits.

How do hormones regulate cellular activities according to Campbell Biology?

Hormones regulate cellular activities by binding to specific receptors on target cells, triggering signaling pathways that ultimately lead to changes in gene expression, protein synthesis, and other cellular processes.

What is the difference between a haploid and diploid cell in Campbell Biology?

A haploid cell has one set of chromosomes, while a diploid cell has two sets of chromosomes. Haploid cells are typically found in gametes (sperm and egg cells), while diploid cells are found in somatic tissues.

What is the process of transcription in gene expression as explained in Campbell Biology?

Transcription is the process of creating a complementary RNA molecule from a DNA template, which is the first step in gene expression and allows for the transmission of genetic information from DNA to the rest of the cell.
