

CAUSES OF ROCK CHANGE

CAUSES OF ROCK CHANGE: A COMPREHENSIVE EXPLORATION OF GEOLOGICAL TRANSFORMATIONS

CAUSES OF ROCK CHANGE ARE FUNDAMENTAL TO UNDERSTANDING THE DYNAMIC NATURE OF OUR PLANET. ROCKS ARE NOT STATIC ENTITIES; THEY ARE CONSTANTLY UNDERGOING TRANSFORMATIONS DRIVEN BY A MYRIAD OF INTERNAL AND EXTERNAL FORCES. THESE PROCESSES, COLLECTIVELY KNOWN AS THE ROCK CYCLE, SHAPE EARTH'S LANDSCAPES, INFLUENCE MINERAL FORMATION, AND DICTATE THE AVAILABILITY OF CRUCIAL RESOURCES. FROM THE IMMENSE HEAT AND PRESSURE DEEP WITHIN THE EARTH'S CRUST TO THE RELENTLESS FORCES OF WEATHER AND EROSION ON THE SURFACE, EVERY ROCK TELLS A STORY OF ITS GEOLOGICAL JOURNEY. THIS ARTICLE DELVES INTO THE PRIMARY AGENTS RESPONSIBLE FOR ALTERING ROCK COMPOSITIONS, STRUCTURES, AND FORMS, PROVIDING A DETAILED OVERVIEW OF BOTH PHYSICAL AND CHEMICAL WEATHERING, THE IMPACT OF TECTONIC ACTIVITY, AND THE TRANSFORMATIVE POWER OF HEAT AND PRESSURE.

CONCLUSION: THE EVER-EVOLVING EARTH

THE PRIMARY AGENTS OF ROCK CHANGE

THE EARTH'S CRUST IS A VAST LABORATORY WHERE ROCKS ARE PERPETUALLY RESHAPED BY A COMPLEX INTERPLAY OF FORCES. THESE FORCES CAN BE BROADLY CATEGORIZED INTO THOSE ORIGINATING FROM WITHIN THE PLANET, SUCH AS TECTONIC PLATE MOVEMENTS AND VOLCANIC ACTIVITY, AND THOSE ORIGINATING FROM EXTERNAL ENVIRONMENTAL FACTORS LIKE CLIMATE, WATER, WIND, AND BIOLOGICAL ORGANISMS. UNDERSTANDING THESE PRIMARY AGENTS IS CRUCIAL FOR DECIPHERING GEOLOGICAL HISTORY AND PREDICTING FUTURE LANDFORM EVOLUTION. THE CONSTANT BOMBARDMENT OF ENERGY, WHETHER THERMAL OR KINETIC, ENSURES THAT THE LITHOSPHERE IS IN A PERPETUAL STATE OF FLUX, WITH OLDER ROCKS YIELDING TO NEW FORMATIONS AND EXISTING STRUCTURES BEING ERODED AND REFORMED.

THESE AGENTS WORK IN CONCERT, OFTEN EXACERBATING EACH OTHER'S EFFECTS. FOR INSTANCE, THE PHYSICAL BREAKDOWN OF ROCKS BY WEATHERING CAN INCREASE THE SURFACE AREA AVAILABLE FOR CHEMICAL REACTIONS, WHILE TECTONIC UPLIFT CAN EXPOSE PREVIOUSLY BURIED ROCKS TO THE ERODIVE POWER OF THE ELEMENTS. THE VERY ESSENCE OF GEOLOGY LIES IN UNRAVELING THESE INTRICATE RELATIONSHIPS AND UNDERSTANDING THE TIMESCALES OVER WHICH THESE PROFOUND TRANSFORMATIONS OCCUR. THE DIVERSITY OF ROCK TYPES FOUND ACROSS THE GLOBE IS A TESTAMENT TO THE VARIED AND POWERFUL PROCESSES THAT HAVE SHAPED THEM OVER EONS.

PHYSICAL WEATHERING: THE MECHANICAL BREAKDOWN OF ROCKS

PHYSICAL WEATHERING, ALSO KNOWN AS MECHANICAL WEATHERING, REFERS TO THE PROCESSES THAT BREAK DOWN ROCKS INTO SMALLER PIECES WITHOUT CHANGING THEIR CHEMICAL COMPOSITION. THESE PROCESSES ARE DRIVEN BY MECHANICAL FORCES AND ARE MOST EFFECTIVE IN ENVIRONMENTS WITH SIGNIFICANT TEMPERATURE FLUCTUATIONS, FROST ACTION, OR ABRASIVE FORCES. THE FRAGMENTATION OF ROCKS INCREASES THE SURFACE AREA AVAILABLE FOR CHEMICAL WEATHERING AND EROSION, PLAYING A CRUCIAL ROLE IN THE INITIAL STAGES OF ROCK DEGRADATION.

FROST WEDGING

FROST WEDGING IS A SIGNIFICANT PHYSICAL WEATHERING PROCESS, PARTICULARLY IN TEMPERATE AND POLAR REGIONS. IT OCCURS WHEN WATER SEEPS INTO CRACKS AND PORES IN ROCKS. AS TEMPERATURES DROP BELOW FREEZING, THE WATER TURNS TO ICE, EXPANDING BY APPROXIMATELY 9% IN VOLUME. THIS EXPANSION EXERTS IMMENSE PRESSURE ON THE SURROUNDING ROCK. REPEATED CYCLES OF FREEZING AND THAWING CAUSE THE CRACKS TO WIDEN AND DEEPEN, EVENTUALLY LEADING TO THE ROCK BREAKING APART. EVIDENCE OF FROST WEDGING CAN BE SEEN IN THE TALUS SLOPES FOUND AT THE BASE OF CLIFFS, WHERE ANGULAR ROCK FRAGMENTS HAVE ACCUMULATED.

THERMAL EXPANSION AND CONTRACTION

ROCKS ARE COMPOSED OF VARIOUS MINERALS, EACH WITH A SLIGHTLY DIFFERENT COEFFICIENT OF THERMAL EXPANSION. WHEN ROCKS ARE EXPOSED TO SIGNIFICANT TEMPERATURE CHANGES, SUCH AS DURING THE DAY-NIGHT CYCLE IN DESERTS OR THROUGH FOREST FIRES, THE MINERALS EXPAND AND CONTRACT AT DIFFERENT RATES. THIS DIFFERENTIAL EXPANSION AND CONTRACTION CREATES INTERNAL STRESSES WITHIN THE ROCK. OVER TIME, THESE STRESSES CAN CAUSE THE ROCK TO FRACTURE AND BREAK APART, A PROCESS KNOWN AS EXFOLIATION OR UNLOADING WEATHERING WHEN IT OCCURS ON LARGE ROCK MASSES EXPOSED BY EROSION OF OVERLYING MATERIAL.

ABRASION

ABRASION IS THE PROCESS BY WHICH ROCKS ARE WORN DOWN BY THE GRINDING AND SCRAPING ACTION OF OTHER ROCKS OR PARTICLES. THIS COMMONLY OCCURS IN ENVIRONMENTS WHERE ROCKS ARE TRANSPORTED BY AGENTS LIKE RIVERS, GLACIERS, OR WIND. FOR EXAMPLE, SEDIMENT-LADEN RIVERS CARRY ABRASIVE PARTICLES THAT SCOUR THE RIVERBED AND BANKS. GLACIERS, WITH THEIR IMMENSE WEIGHT AND THE EMBEDDED ROCKS WITHIN THEM, ACT AS POWERFUL GRINDING TOOLS, CARVING OUT VALLEYS AND POLISHING BEDROCK. WINDBLOWN SAND CAN ALSO EFFECTIVELY ABRAD E EXPOSED ROCK SURFACES, CREATING DISTINCTIVE FEATURES LIKE VENTIFACTS.

ROOT WEDGING

BIOLOGICAL AGENTS CAN ALSO CONTRIBUTE TO PHYSICAL WEATHERING. PLANT ROOTS, AS THEY GROW, CAN EXERT PRESSURE ON CRACKS IN ROCKS. WHILE INDIVIDUAL ROOTS MAY EXERT ONLY A SMALL FORCE, OVER TIME, A DENSE NETWORK OF ROOTS CAN WIDEN EXISTING FISSURES, LEADING TO ROCK FRAGMENTATION. THIS PROCESS IS PARTICULARLY EVIDENT IN AREAS WITH DENSE VEGETATION AND ROCKY SOIL, WHERE TREE ROOTS CAN BREAK APART BOULDERS AND DISLODGE ROCKS.

CHEMICAL WEATHERING: THE MOLECULAR ALTERATION OF ROCKS

CHEMICAL WEATHERING INVOLVES THE DECOMPOSITION OF ROCKS THROUGH CHEMICAL REACTIONS, LEADING TO CHANGES IN THEIR MINERAL COMPOSITION AND STRUCTURE. THESE PROCESSES ARE SIGNIFICANTLY INFLUENCED BY THE PRESENCE OF WATER, OXYGEN, AND ACIDIC SUBSTANCES. CHEMICAL WEATHERING IS GENERALLY MORE EFFECTIVE IN WARM, HUMID CLIMATES WHERE WATER IS ABUNDANT AND CHEMICAL REACTIONS PROCEED MORE RAPIDLY. IT BREAKS DOWN MINERALS, TRANSFORMING THEM INTO NEW SUBSTANCES THAT ARE OFTEN MORE SUSCEPTIBLE TO PHYSICAL WEATHERING.

DISSOLUTION

DISSOLUTION IS THE PROCESS WHERE MINERALS ARE DISSOLVED BY WATER, OFTEN AIDED BY THE PRESENCE OF ACIDS. CARBONIC ACID, FORMED WHEN CARBON DIOXIDE DISSOLVES IN WATER, IS A COMMON AGENT OF DISSOLUTION. THIS IS PARTICULARLY EFFECTIVE IN DISSOLVING CARBONATE ROCKS LIKE LIMESTONE AND MARBLE, LEADING TO THE FORMATION OF CAVES AND KARST TOPOGRAPHY. MANY SOLUBLE MINERALS, SUCH AS HALITE (ROCK SALT) AND GYPSUM, DISSOLVE READILY IN PURE WATER.

Oxidation

Oxidation is a chemical reaction in which a substance loses electrons, typically by reacting with oxygen. In rocks, this process is most commonly observed in minerals containing iron. When iron-bearing minerals are exposed to oxygen and water, they rust, forming iron oxides and hydroxides, such as hematite and limonite. This process causes the rock to weaken and crumble, often resulting in a reddish-brown discoloration. For example, the rusting of pyrite (fool's gold) in shales can lead to their disintegration.

Hydrolysis

Hydrolysis is a chemical reaction in which water breaks down minerals. In this process, water molecules split, and hydrogen ions and hydroxide ions react with the mineral's constituent ions. This is a particularly important weathering process for silicate minerals, which are the most abundant minerals in Earth's crust. For instance, feldspar, a common mineral, undergoes hydrolysis to form clay minerals, silica, and dissolved ions. This transformation weakens the rock structure and makes it more prone to erosion.

Acid Hydrolysis and Carbonation

While pure water can cause hydrolysis, the presence of acids significantly accelerates the process. Carbonic acid, as mentioned, is a key player. Rainfall absorbs atmospheric carbon dioxide, forming a weak acid. When this acidic rainwater interacts with rocks, it can break down mineral structures. This process, known as carbonation, is a primary factor in the weathering of many common rock-forming minerals, including feldspars and micas, contributing to the formation of clays and soluble salts.

The Role of Biological Activity in Rock Change

Living organisms, from microscopic bacteria to large trees and burrowing animals, also contribute to the alteration of rocks. Their influence can be both physical and chemical, often exacerbating the effects of other weathering processes.

Plant Roots

As previously mentioned, plant roots contribute to physical weathering by wedging apart rock fragments. Additionally, plant roots release organic acids and carbon dioxide as they respire, which can enhance chemical weathering, particularly in the soil layer. This slow but persistent action can break down minerals and contribute to soil formation over long periods.

Microbial Activity

Microorganisms, such as bacteria and fungi, play a significant role in chemical weathering. Many microbes secrete organic acids and chelating agents that can break down mineral structures and facilitate the dissolution of rock components. Some bacteria are involved in redox reactions, such as the oxidation of iron and sulfur, which can alter mineral stability and contribute to rock decomposition. The biofilms formed by microbes on rock surfaces can also trap moisture and organic matter, creating microenvironments conducive to further chemical reactions.

ANIMAL ACTIVITY

BURROWING ANIMALS, LIKE EARTHWORMS, RODENTS, AND ANTS, PHYSICALLY MIX AND CHURN SOIL AND ROCK FRAGMENTS. THIS ACTIVITY CAN EXPOSE FRESH ROCK SURFACES TO WEATHERING PROCESSES AND ALSO AID IN THE INFILTRATION OF WATER, PROMOTING BOTH PHYSICAL AND CHEMICAL BREAKDOWN. IN COASTAL ENVIRONMENTS, ORGANISMS LIKE BIVALVES AND SPONGES CAN BORE INTO ROCKS, CONTRIBUTING TO THEIR EROSION AND FRAGMENTATION.

METAMORPHISM: TRANSFORMATION BY HEAT AND PRESSURE

METAMORPHISM IS A GEOLOGICAL PROCESS THAT TRANSFORMS EXISTING ROCKS (PROTOLITHS) INTO NEW TYPES OF ROCKS THROUGH THE INFLUENCE OF HEAT, PRESSURE, AND CHEMICALLY ACTIVE FLUIDS, WITHOUT MELTING THE ORIGINAL ROCK. THESE TRANSFORMATIONS OCCUR DEEP WITHIN THE EARTH'S CRUST AND UPPER MANTLE, WHERE CONDITIONS ARE VASTLY DIFFERENT FROM THE SURFACE. THE CHANGES INVOLVE RECRYSTALLIZATION OF MINERALS, FORMATION OF NEW MINERALS, AND OFTEN A REORIENTATION OF MINERAL GRAINS, LEADING TO CHARACTERISTIC TEXTURES AND STRUCTURES IN METAMORPHIC ROCKS.

CONTACT METAMORPHISM

CONTACT METAMORPHISM OCCURS WHEN ROCKS ARE EXPOSED TO HIGH TEMPERATURES ASSOCIATED WITH A MAGMATIC INTRUSION. AS MAGMA RISES THROUGH THE CRUST, IT HEATS THE SURROUNDING COUNTRY ROCKS. THE DEGREE OF METAMORPHISM IS GREATEST CLOSEST TO THE INTRUSION AND DECREASES WITH DISTANCE. THIS TYPE OF METAMORPHISM IS CHARACTERIZED BY AN INCREASE IN TEMPERATURE AND A RELATIVELY LOW PRESSURE. THE RESULTING METAMORPHIC ROCKS ARE OFTEN FINE-GRAINED AND MAY SHOW NEW MINERAL ASSEMBLAGES THAT ARE STABLE AT HIGH TEMPERATURES.

REGIONAL METAMORPHISM

REGIONAL METAMORPHISM OCCURS OVER LARGE AREAS, TYPICALLY ASSOCIATED WITH MOUNTAIN-BUILDING EVENTS AND THE COLLISION OF TECTONIC PLATES. IN THESE SETTINGS, ROCKS ARE SUBJECTED TO BOTH HIGH TEMPERATURES AND HIGH PRESSURES. THE IMMENSE FORCES INVOLVED CAN CAUSE DEFORMATION, FOLDING, AND FAULTING OF ROCK LAYERS. THIS TYPE OF METAMORPHISM RESULTS IN A WIDE VARIETY OF METAMORPHIC ROCKS, RANGING FROM SLATES AND SCHISTS TO GNEISSES, OFTEN EXHIBITING FOLIATION – A LAYERED OR BANDED APPEARANCE DUE TO THE PARALLEL ALIGNMENT OF PLATY OR ELONGATED MINERAL GRAINS.

HYDROTHERMAL METAMORPHISM

HYDROTHERMAL METAMORPHISM OCCURS WHEN HOT, CHEMICALLY ACTIVE FLUIDS CIRCULATE THROUGH ROCKS, ALTERING THEIR MINERALOGY AND TEXTURE. THESE FLUIDS ARE OFTEN ASSOCIATED WITH MAGMATIC ACTIVITY OR DEEP CIRCULATION OF GROUNDWATER. THEY CAN DISSOLVE EXISTING MINERALS, TRANSPORT THEM, AND DEPOSIT NEW MINERALS, LEADING TO SIGNIFICANT CHANGES IN THE ROCK'S COMPOSITION. THIS PROCESS IS PARTICULARLY IMPORTANT IN AREAS AROUND MID-OCEAN RIDGES AND IN GEOTHERMAL SYSTEMS.

IGNEOUS PROCESSES: MELTING AND SOLIDIFICATION

IGNEOUS ROCKS ARE FORMED FROM THE COOLING AND SOLIDIFICATION OF MOLTEN ROCK MATERIAL, EITHER MAGMA (BENEATH THE SURFACE) OR LAVA (ON THE SURFACE). WHILE IGNEOUS PROCESSES ARE PRIMARILY ABOUT ROCK FORMATION, THE CONDITIONS UNDER WHICH THIS OCCURS, INCLUDING THE MELTING OF PRE-EXISTING ROCKS, ARE A SIGNIFICANT CAUSE OF ROCK CHANGE.

MELTING OF PRE-EXISTING ROCKS

WHEN EXISTING ROCKS ARE SUBJECTED TO SUFFICIENTLY HIGH TEMPERATURES, THEY CAN MELT TO FORM MAGMA. THIS MELTING CAN OCCUR DUE TO HEAT FROM EARTH'S INTERIOR, FRICTIONAL HEATING AT TECTONIC PLATE BOUNDARIES, OR THE ADDITION OF VOLATILE SUBSTANCES LIKE WATER. THE COMPOSITION OF THE RESULTING MAGMA DEPENDS ON THE COMPOSITION OF THE SOURCE ROCK AND THE DEGREE OF MELTING. THIS PROCESS EFFECTIVELY DESTROYS THE ORIGINAL ROCK, TRANSFORMING IT INTO A COMPLETELY NEW, MOLTEN STATE THAT WILL EVENTUALLY SOLIDIFY INTO AN IGNEOUS ROCK.

SOLIDIFICATION OF MAGMA AND LAVA

ONCE MOLTEN ROCK MATERIAL HAS FORMED, ITS SUBSEQUENT COOLING AND SOLIDIFICATION LEAD TO THE FORMATION OF IGNEOUS ROCKS. THE RATE OF COOLING SIGNIFICANTLY INFLUENCES THE TEXTURE OF THE RESULTING ROCK. SLOW COOLING, TYPICALLY OCCURRING BENEATH THE EARTH'S SURFACE (INTRUSIVE IGNEOUS ROCKS), ALLOWS FOR THE FORMATION OF LARGE CRYSTALS, RESULTING IN COARSE-GRAINED TEXTURES LIKE GRANITE. RAPID COOLING, ON THE SURFACE (EXTRUSIVE IGNEOUS ROCKS), PREVENTS THE FORMATION OF LARGE CRYSTALS, LEADING TO FINE-GRAINED TEXTURES LIKE BASALT OR GLASSY TEXTURES LIKE OBSIDIAN.

SEDIMENTARY PROCESSES: COMPACTION AND CEMENTATION

SEDIMENTARY ROCKS ARE FORMED FROM THE ACCUMULATION AND LITHIFICATION OF SEDIMENT. THIS LITHIFICATION PROCESS, WHICH INCLUDES COMPACTION AND CEMENTATION, IS A CRUCIAL CAUSE OF ROCK CHANGE, TRANSFORMING LOOSE PARTICLES INTO SOLID ROCK.

COMPACTION

AS LAYERS OF SEDIMENT ACCUMULATE, THE WEIGHT OF THE OVERLYING MATERIAL COMPRESSES THE LOWER LAYERS. THIS PROCESS, KNOWN AS COMPACTION, REDUCES THE PORE SPACE BETWEEN SEDIMENT GRAINS AND SQUEEZES OUT MUCH OF THE WATER TRAPPED WITHIN THE SEDIMENT. THE REDUCTION IN VOLUME AND PORE SPACE CAN SIGNIFICANTLY ALTER THE PHYSICAL PROPERTIES OF THE SEDIMENT, MAKING IT DENSER AND MORE COHESIVE.

CEMENTATION

FOLLOWING COMPACTION, DISSOLVED MINERALS IN THE GROUNDWATER CIRCULATING THROUGH THE SEDIMENT CAN PRECIPITATE IN THE REMAINING PORE SPACES. THESE PRECIPITATED MINERALS ACT AS A NATURAL GLUE, BINDING THE SEDIMENT GRAINS TOGETHER. COMMON CEMENTING AGENTS INCLUDE SILICA (QUARTZ), CALCITE (CALCIUM CARBONATE), AND IRON OXIDES. THIS CEMENTATION PROCESS IS CRITICAL IN TRANSFORMING LOOSE SEDIMENT, SUCH AS SAND OR MUD, INTO SOLID SEDIMENTARY ROCKS LIKE SANDSTONE, LIMESTONE, AND SHALE.

THE RELENTLESS FORCES OF NATURE, FROM THE SUBTLE DRIP OF WATER TO THE CATAclysmic shifts of tectonic plates, are continuously at work, orchestrating the grand ballet of rock transformation. UNDERSTANDING THE CAUSES OF ROCK CHANGE NOT ONLY ILLUMINATES THE GEOLOGICAL HISTORY OF OUR PLANET BUT ALSO PROVIDES INSIGHTS INTO THE FORMATION OF VALUABLE MINERAL DEPOSITS AND THE DYNAMIC PROCESSES THAT SHAPE OUR LANDSCAPES. THE ROCK CYCLE IS A TESTAMENT TO EARTH'S ENDURING POWER TO RENEW AND RESHAPE ITSELF, A CONTINUOUS PROCESS THAT HAS BEEN ONGOING FOR BILLIONS OF YEARS.

FAQ

Q: WHAT ARE THE MAIN CATEGORIES OF CAUSES OF ROCK CHANGE?

A: THE MAIN CATEGORIES OF CAUSES OF ROCK CHANGE ARE PHYSICAL WEATHERING, CHEMICAL WEATHERING, BIOLOGICAL ACTIVITY, METAMORPHISM, IGNEOUS PROCESSES (MELTING AND SOLIDIFICATION), AND SEDIMENTARY PROCESSES (COMPACTION AND CEMENTATION).

Q: HOW DOES TEMPERATURE AFFECT THE CAUSES OF ROCK CHANGE?

A: TEMPERATURE PLAYS A SIGNIFICANT ROLE IN BOTH PHYSICAL AND CHEMICAL WEATHERING. EXTREME TEMPERATURE FLUCTUATIONS CAN CAUSE THERMAL EXPANSION AND CONTRACTION, LEADING TO PHYSICAL BREAKDOWN. HIGHER TEMPERATURES GENERALLY ACCELERATE CHEMICAL REACTIONS, MAKING CHEMICAL WEATHERING MORE EFFECTIVE IN WARMER CLIMATES. HEAT IS ALSO A PRIMARY DRIVER OF METAMORPHISM AND THE MELTING OF ROCKS TO FORM MAGMA.

Q: IS EROSION CONSIDERED A CAUSE OF ROCK CHANGE?

A: EROSION IS THE PROCESS OF TRANSPORTING WEATHERED MATERIAL, RATHER THAN DIRECTLY BREAKING DOWN ROCKS. HOWEVER, EROSION IS INTRINSICALLY LINKED TO ROCK CHANGE BECAUSE IT REMOVES WEATHERED MATERIAL, EXPOSING FRESH ROCK SURFACES TO FURTHER WEATHERING AND ALTERATION. AGENTS OF EROSION LIKE WATER, WIND, AND ICE CAN ALSO CONTRIBUTE TO PHYSICAL BREAKDOWN THROUGH ABRASION.

Q: HOW DO TECTONIC PLATE MOVEMENTS CONTRIBUTE TO ROCK CHANGE?

A: TECTONIC PLATE MOVEMENTS ARE RESPONSIBLE FOR SIGNIFICANT ROCK CHANGE THROUGH PROCESSES LIKE REGIONAL METAMORPHISM, WHERE ROCKS ARE SUBJECTED TO IMMENSE HEAT AND PRESSURE DURING MOUNTAIN BUILDING. PLATE TECTONICS ALSO DRIVES VOLCANIC ACTIVITY, LEADING TO THE FORMATION OF NEW IGNEOUS ROCKS, AND CAN CAUSE UPLIFT AND SUBSIDENCE, EXPOSING OR BURYING ROCKS AND INFLUENCING WEATHERING AND EROSION PATTERNS.

Q: CAN HUMAN ACTIVITIES CAUSE ROCK CHANGE?

A: YES, HUMAN ACTIVITIES CAN CAUSE ROCK CHANGE, ALBEIT OFTEN ON A LOCALIZED SCALE OR AT AN ACCELERATED RATE COMPARED TO NATURAL PROCESSES. MINING OPERATIONS PHYSICALLY BREAK APART AND REMOVE ROCK. CONSTRUCTION AND INFRASTRUCTURE DEVELOPMENT ALTER LANDSCAPES AND EXPOSE ROCKS TO WEATHERING. POLLUTION, PARTICULARLY ACID RAIN, CAN ACCELERATE CHEMICAL WEATHERING. FURTHERMORE, ACTIVITIES LIKE QUARRYING AND DAM CONSTRUCTION DIRECTLY MANIPULATE ROCK FORMATIONS.

Q: WHAT IS THE DIFFERENCE BETWEEN PHYSICAL AND CHEMICAL WEATHERING?

A: PHYSICAL WEATHERING BREAKS ROCKS INTO SMALLER PIECES THROUGH MECHANICAL FORCES, SUCH AS FROST WEDGING, ABRASION, AND THERMAL EXPANSION, WITHOUT CHANGING THEIR CHEMICAL COMPOSITION. CHEMICAL WEATHERING, ON THE OTHER HAND, ALTERS THE CHEMICAL COMPOSITION OF ROCKS THROUGH REACTIONS LIKE DISSOLUTION, OXIDATION, AND HYDROLYSIS, TRANSFORMING MINERALS INTO NEW SUBSTANCES.
