

CO₂ EMISSIONS OCEAN IMPACTS

CO₂ EMISSIONS OCEAN IMPACTS ARE PROFOUND AND FAR-REACHING, FUNDAMENTALLY ALTERING MARINE ECOSYSTEMS AND THE LIFE THEY SUPPORT. AS ATMOSPHERIC CARBON DIOXIDE LEVELS RISE DUE TO HUMAN ACTIVITIES, THE OCEAN ABSORBS A SIGNIFICANT PORTION OF THIS EXCESS CO₂, LEADING TO A CASCADE OF DETRIMENTAL EFFECTS. THIS ARTICLE WILL DELVE INTO THE MULTIFACETED CONSEQUENCES OF INCREASED CO₂ ABSORPTION BY THE OCEANS, EXPLORING TOPICS SUCH AS OCEAN ACIDIFICATION, DEOXYGENATION, RISING SEA LEVELS, AND THEIR IMPACTS ON MARINE BIODIVERSITY, FISHERIES, AND COASTAL COMMUNITIES. UNDERSTANDING THESE CRITICAL INTERCONNECTIONS IS VITAL FOR DEVELOPING EFFECTIVE MITIGATION AND ADAPTATION STRATEGIES TO PROTECT OUR PLANET'S LARGEST AND MOST VITAL ECOSYSTEM.

THE OCEAN'S CARBON SINK FUNCTION AND THE RISE OF CO₂ EMISSIONS

THE EARTH'S OCEANS ACT AS A MASSIVE NATURAL CARBON SINK, ABSORBING A SUBSTANTIAL AMOUNT OF ANTHROPOGENIC CARBON DIOXIDE (CO₂) FROM THE ATMOSPHERE. THIS PROCESS, KNOWN AS THE OCEAN CARBON SINK, HAS BEEN INSTRUMENTAL IN BUFFERING THE PACE OF CLIMATE CHANGE BY SEQUESTERING ROUGHLY 25% OF THE CO₂ RELEASED BY HUMAN ACTIVITIES SINCE THE INDUSTRIAL REVOLUTION. HOWEVER, THIS VITAL SERVICE COMES AT A SIGNIFICANT COST TO THE MARINE ENVIRONMENT. THE CONTINUOUS INFLUX OF CO₂ IS ALTERING THE FUNDAMENTAL CHEMISTRY OF SEAWATER, TRIGGERING A CHAIN OF REACTIONS WITH SEVERE ECOLOGICAL AND ECONOMIC IMPLICATIONS.

THE OCEAN'S CAPACITY TO ABSORB CO₂ IS DRIVEN BY SEVERAL PHYSICAL AND BIOLOGICAL PROCESSES. DISSOLUTION OF CO₂ INTO SURFACE WATERS IS A PRIMARY MECHANISM, WHERE THE GAS READILY DISSOLVES IN SEAWATER. PHYTOPLANKTON, MICROSCOPIC MARINE PLANTS, ALSO PLAY A CRUCIAL ROLE THROUGH PHOTOSYNTHESIS, CONVERTING DISSOLVED CO₂ INTO ORGANIC MATTER. WHEN THESE ORGANISMS DIE, SOME OF THIS ORGANIC CARBON SINKS TO THE DEEP OCEAN, EFFECTIVELY REMOVING IT FROM THE ATMOSPHERE FOR EXTENDED PERIODS. HOWEVER, THE SHEER VOLUME OF CO₂ BEING EMITTED INTO THE ATMOSPHERE IS OVERWHELMING THESE NATURAL ABSORPTION MECHANISMS, PUSHING THE OCEAN SYSTEM TOWARDS A CRITICAL TIPPING POINT.

THE CHEMISTRY OF OCEAN ACIDIFICATION EXPLAINED

OCEAN ACIDIFICATION IS A DIRECT CONSEQUENCE OF THE OCEAN ABSORBING EXCESS ATMOSPHERIC CO₂. WHEN CO₂ DISSOLVES IN SEAWATER, IT UNDERGOES A SERIES OF CHEMICAL REACTIONS. INITIALLY, CO₂ REACTS WITH WATER TO FORM CARBONIC ACID (H₂CO₃). THIS CARBONIC ACID THEN DISSOCIATES, RELEASING HYDROGEN IONS (H⁺) AND BICARBONATE IONS (HCO₃⁻). THE INCREASE IN HYDROGEN IONS LEADS TO A DECREASE IN THE OCEAN'S pH, MAKING IT MORE ACIDIC. SIMULTANEOUSLY, THE INCREASED CONCENTRATION OF BICARBONATE IONS MEANS THAT FEWER CARBONATE IONS (CO₃²⁻) ARE AVAILABLE. CARBONATE IONS ARE ESSENTIAL BUILDING BLOCKS FOR MANY MARINE ORGANISMS THAT CONSTRUCT SHELLS AND SKELETONS FROM CALCIUM CARBONATE.

THE ONGOING ABSORPTION OF CO₂ IS CAUSING A STEADY DECLINE IN THE OCEAN'S pH. PRIOR TO THE INDUSTRIAL ERA, THE AVERAGE pH OF SURFACE OCEAN WATER WAS AROUND 8.2. TODAY, IT HAS DROPPED TO APPROXIMATELY 8.1, REPRESENTING A 30% INCREASE IN ACIDITY. PROJECTIONS INDICATE THAT BY THE END OF THIS CENTURY, THE OCEAN'S pH COULD FALL FURTHER, POTENTIALLY REACHING LEVELS NOT SEEN FOR MILLIONS OF YEARS. THIS SHIFT IN OCEAN CHEMISTRY, THOUGH SEEMINGLY SMALL IN NUMERICAL TERMS, REPRESENTS A SIGNIFICANT ALTERATION OF THE MARINE ENVIRONMENT'S FOUNDATIONAL CONDITIONS. THE INCREASED ACIDITY ALSO AFFECTS THE SATURATION STATE OF CALCIUM CARBONATE MINERALS, MAKING IT HARDER FOR CALCIFYING ORGANISMS TO FORM AND MAINTAIN THEIR STRUCTURES.

IMPACTS OF OCEAN ACIDIFICATION ON MARINE LIFE

THE BIOLOGICAL RAMIFICATIONS OF OCEAN ACIDIFICATION ARE EXTENSIVE AND CAN BE OBSERVED ACROSS VARIOUS MARINE TROPHIC LEVELS. CALCIFYING ORGANISMS, SUCH AS CORALS, SHELLFISH, PLANKTON, AND CRUSTACEANS, ARE PARTICULARLY VULNERABLE. THE REDUCED AVAILABILITY OF CARBONATE IONS AND THE INCREASED ACIDITY MAKE IT ENERGETICALLY MORE DEMANDING FOR THESE SPECIES TO BUILD AND MAINTAIN THEIR SHELLS AND SKELETONS. IN SOME CASES, EXISTING SHELLS AND SKELETONS CAN EVEN BEGIN TO DISSOLVE.

THE EFFECTS EXTEND BEYOND CALCIFIERS. FISH LARVAE MAY EXPERIENCE IMPAIRED DEVELOPMENT AND SENSORY ABILITIES, AFFECTING THEIR ABILITY TO FIND FOOD OR AVOID PREDATORS. THE PHYSIOLOGY AND BEHAVIOR OF MANY MARINE SPECIES CAN BE DISRUPTED, IMPACTING THEIR GROWTH RATES, REPRODUCTIVE SUCCESS, AND SURVIVAL. FOR INSTANCE, SOME STUDIES HAVE SHOWN THAT CHANGES IN SEAWATER CHEMISTRY CAN ALTER FISH OLFACTION, MAKING IT HARDER FOR THEM TO DETECT PREDATORS OR LOCATE SUITABLE HABITATS. THESE CASCADING EFFECTS CAN LEAD TO SHIFTS IN COMMUNITY STRUCTURE AND THE FUNCTIONING OF ENTIRE MARINE ECOSYSTEMS. THE INTRICATE WEB OF MARINE LIFE IS BEING STRAINED BY THIS FUNDAMENTAL CHEMICAL CHANGE.

DEOXYGENATION: THE OCEAN'S GROWING OXYGEN CRISIS

ANOTHER CRITICAL CONSEQUENCE OF RISING CO₂ EMISSIONS IS OCEAN DEOXYGENATION, A PROCESS WHERE THE OCEAN LOSES DISSOLVED OXYGEN. THIS PHENOMENON IS DRIVEN BY TWO PRIMARY MECHANISMS LINKED TO CLIMATE CHANGE. FIRSTLY, WARMER WATER HOLDS LESS DISSOLVED OXYGEN THAN COLDER WATER. AS GLOBAL TEMPERATURES RISE, OCEAN SURFACE WATERS ARE WARMING, REDUCING THEIR CAPACITY TO STORE OXYGEN. SECONDLY, INCREASED STRATIFICATION OF THE OCEAN, CAUSED BY WARMING SURFACE WATERS AND REDUCED MIXING, LIMITS THE SUPPLY OF OXYGEN FROM THE SURFACE TO DEEPER OCEAN LAYERS. FURTHERMORE, INCREASED NUTRIENT RUNOFF FROM LAND, OFTEN EXACERBATED BY CHANGING PRECIPITATION PATTERNS, CAN FUEL ALGAL BLOOMS. WHEN THESE ALGAE DIE AND DECOMPOSE, THE PROCESS CONSUMES LARGE AMOUNTS OF OXYGEN, CREATING "DEAD ZONES" OR AREAS OF HYPOXIA (LOW OXYGEN) AND ANOXIA (NO OXYGEN).

THE INTERCONNECTEDNESS OF CO₂ EMISSIONS AND DEOXYGENATION IS UNDENIABLE. WHILE OCEAN ACIDIFICATION DIRECTLY ALTERS SEAWATER CHEMISTRY, DEOXYGENATION CREATES PHYSIOLOGICAL STRESS FOR MARINE ORGANISMS BY LIMITING THEIR ACCESS TO ESSENTIAL OXYGEN. THESE TWO STRESSORS CAN ACT SYNERGISTICALLY, COMPOUNDING THE NEGATIVE IMPACTS ON MARINE LIFE AND ECOSYSTEMS. THE EXPANSION OF OXYGEN MINIMUM ZONES (OMZs) IS A SIGNIFICANT CONCERN, AS THESE AREAS BECOME UNINHABITABLE FOR MANY SPECIES, FORCING THEM TO MIGRATE OR PERISH. THIS LEADS TO A REDUCTION IN AVAILABLE HABITAT AND POTENTIAL DISRUPTIONS TO FOOD WEBS.

CONSEQUENCES OF OCEAN DEOXYGENATION

THE LOSS OF OXYGEN IN THE OCEAN HAS SEVERE CONSEQUENCES FOR MARINE LIFE AND ECOSYSTEMS. ORGANISMS THAT REQUIRE OXYGEN FOR RESPIRATION, SUCH AS FISH, CRUSTACEANS, AND MANY INVERTEBRATES, STRUGGLE TO SURVIVE IN LOW-OXYGEN ENVIRONMENTS. SPECIES THAT CAN TOLERATE LOWER OXYGEN LEVELS MAY EXPERIENCE REDUCED GROWTH RATES, IMPAIRED REPRODUCTION, AND INCREASED SUSCEPTIBILITY TO DISEASE. MOBILE SPECIES MAY BE FORCED TO ABANDON THEIR HABITATS, LEADING TO SHIFTS IN SPECIES DISTRIBUTION AND BIODIVERSITY LOSS.

FOR SESSILE ORGANISMS AND THOSE WITH LIMITED MOBILITY, DEOXYGENATION CAN BE A DEATH SENTENCE. ENTIRE BENTHIC COMMUNITIES, INCLUDING CORALS AND SHELLFISH BEDS, CAN BE WIPED OUT WHEN OXYGEN LEVELS DROP TOO LOW. THE ECONOMIC IMPLICATIONS ARE ALSO SUBSTANTIAL. MANY COMMERCIALY IMPORTANT FISH SPECIES ARE SENSITIVE TO LOW OXYGEN LEVELS AND ARE THEREFORE AFFECTED BY EXPANDING DEAD ZONES. FISHERIES CAN EXPERIENCE SIGNIFICANT DECLINES IN CATCH AS FISH POPULATIONS ARE FORCED TO MOVE OR THEIR HABITATS BECOME UNSUITABLE. THE HEALTH AND PRODUCTIVITY OF MARINE ECOSYSTEMS ARE INTRINSICALLY LINKED TO OXYGEN AVAILABILITY, MAKING DEOXYGENATION A PROFOUND THREAT TO MARINE BIODIVERSITY AND HUMAN RELIANCE ON OCEAN RESOURCES.

RIISING SEA LEVELS: A DIRECT THREAT TO COASTAL REGIONS

WHILE OCEAN ACIDIFICATION AND DEOXYGENATION ARE CHEMICAL AND BIOLOGICAL SHIFTS, RISING SEA LEVELS REPRESENT A MORE DIRECT PHYSICAL MANIFESTATION OF CLIMATE CHANGE LINKED TO CO₂ EMISSIONS. THE PRIMARY DRIVERS OF SEA-LEVEL RISE ARE THE THERMAL EXPANSION OF SEAWATER AND THE MELTING OF LAND-BASED ICE, SUCH AS GLACIERS AND ICE SHEETS. AS THE OCEAN WARMS, WATER EXPANDS, OCCUPYING A LARGER VOLUME. SIMULTANEOUSLY, THE INFLUX OF MELTWATER FROM

GLACIERS AND ICE SHEETS ADDS MORE WATER TO THE OCEANS.

THE CONSEQUENCES OF RISING SEA LEVELS ARE ALREADY BEING FELT GLOBALLY, PARTICULARLY IN LOW-LYING COASTAL AREAS. INCREASED COASTAL EROSION, MORE FREQUENT AND SEVERE COASTAL FLOODING, SALTWATER INTRUSION INTO FRESHWATER AQUIFERS, AND THE INUNDATION OF COASTAL WETLANDS ARE ALL DIRECT IMPACTS. THESE CHANGES THREATEN COASTAL INFRASTRUCTURE, HOMES, AGRICULTURAL LAND, AND VITAL COASTAL ECOSYSTEMS LIKE MANGROVES AND SALT MARSHES, WHICH SERVE AS IMPORTANT NURSERIES FOR MARINE LIFE AND NATURAL BUFFERS AGAINST STORMS. THE SOCIOECONOMIC IMPACTS ON COASTAL COMMUNITIES, INCLUDING DISPLACEMENT AND LOSS OF LIVELIHOODS, ARE BECOMING INCREASINGLY SIGNIFICANT.

IMPACTS ON MARINE ECOSYSTEMS AND BIODIVERSITY

THE COMBINED EFFECTS OF OCEAN ACIDIFICATION, DEOXYGENATION, AND RISING SEA LEVELS ARE CREATING A HOSTILE ENVIRONMENT FOR MARINE LIFE AND LEADING TO SIGNIFICANT LOSSES IN BIODIVERSITY. CORAL REEFS, OFTEN REFERRED TO AS THE "RAINFORESTS OF THE SEA" DUE TO THEIR INCREDIBLE BIODIVERSITY, ARE HIGHLY SUSCEPTIBLE TO WARMING WATERS (CAUSING BLEACHING) AND OCEAN ACIDIFICATION, WHICH HINDERS THEIR ABILITY TO GROW AND REPAIR THEMSELVES. THE DEGRADATION OF CORAL REEFS HAS CASCADING EFFECTS THROUGHOUT THE MARINE FOOD WEB, IMPACTING COUNTLESS SPECIES THAT DEPEND ON THEM FOR FOOD AND SHELTER.

SEAGRASS MEADOWS AND KELP FORESTS, WHICH PROVIDE CRITICAL HABITAT AND CARBON SEQUESTRATION SERVICES, ARE ALSO THREATENED BY WARMING WATERS AND ALTERED OCEAN CHEMISTRY. CHANGES IN WATER TEMPERATURE AND OXYGEN LEVELS CAN DISRUPT THE REPRODUCTIVE CYCLES AND SURVIVAL RATES OF MANY FISH SPECIES, INVERTEBRATES, AND MARINE MAMMALS. THE MIGRATION PATTERNS OF SPECIES ARE SHIFTING AS THEY SEEK OUT MORE FAVORABLE CONDITIONS, LEADING TO NOVEL ECOLOGICAL INTERACTIONS AND POTENTIAL MISMATCHES IN PREDATOR-PREY RELATIONSHIPS. THE OVERALL RESILIENCE OF MARINE ECOSYSTEMS IS BEING DIMINISHED, MAKING THEM LESS ABLE TO ADAPT TO FURTHER ENVIRONMENTAL CHANGES.

ECONOMIC AND SOCIETAL REPERCUSSIONS

THE IMPACTS OF CO₂ EMISSIONS ON THE OCEAN HAVE PROFOUND ECONOMIC AND SOCIETAL REPERCUSSIONS. THE DECLINE IN FISH STOCKS DUE TO ACIDIFICATION, DEOXYGENATION, AND HABITAT DEGRADATION DIRECTLY THREATENS THE GLOBAL FISHING INDUSTRY, WHICH PROVIDES A VITAL SOURCE OF PROTEIN AND LIVELIHOODS FOR BILLIONS OF PEOPLE. REDUCED CATCHES AND INCREASED OPERATING COSTS DUE TO ALTERED FISH DISTRIBUTIONS CAN LEAD TO SIGNIFICANT ECONOMIC LOSSES FOR FISHING COMMUNITIES AND COASTAL ECONOMIES.

TOURISM RELIANT ON HEALTHY MARINE ECOSYSTEMS, SUCH AS DIVING AND SNORKELING ON CORAL REEFS, ALSO SUFFERS. THE LOSS OF THESE NATURAL ATTRACTIONS CAN DEVASTATE LOCAL ECONOMIES. FURTHERMORE, THE INCREASED FREQUENCY AND INTENSITY OF COASTAL FLOODING AND STORM SURGES, AMPLIFIED BY RISING SEA LEVELS, NECESSITATE COSTLY ADAPTATIONS AND DISASTER RELIEF EFFORTS. THE DISPLACEMENT OF COASTAL POPULATIONS AND THE LOSS OF CULTURAL HERITAGE ASSOCIATED WITH MARINE ENVIRONMENTS ARE ALSO SIGNIFICANT SOCIETAL CHALLENGES. THE INTERCONNECTEDNESS OF OCEAN HEALTH WITH HUMAN WELL-BEING MEANS THAT THESE ENVIRONMENTAL CHANGES TRANSLATE DIRECTLY INTO HUMAN CHALLENGES.

FUTURE OUTLOOK AND MITIGATION STRATEGIES

THE FUTURE OF OUR OCEANS HINGES ON OUR COLLECTIVE ABILITY TO DRASTICALLY REDUCE CO₂ EMISSIONS. WHILE SOME DEGREE OF OCEAN ACIDIFICATION AND DEOXYGENATION IS ALREADY LOCKED IN DUE TO PAST AND PRESENT EMISSIONS, THE SEVERITY OF FUTURE IMPACTS CAN STILL BE INFLUENCED BY IMMEDIATE AND SUSTAINED ACTION. TRANSITIONING TO RENEWABLE ENERGY SOURCES, IMPROVING ENERGY EFFICIENCY, AND ADOPTING SUSTAINABLE LAND-USE PRACTICES ARE CRUCIAL STEPS IN MITIGATING THE ROOT CAUSE.

BEYOND EMISSION REDUCTIONS, ADAPTATION STRATEGIES ARE ALSO VITAL. THIS INCLUDES PROTECTING AND RESTORING COASTAL HABITATS LIKE MANGROVES AND CORAL REEFS, WHICH CAN ENHANCE RESILIENCE. MARINE PROTECTED AREAS CAN HELP SAFEGUARD BIODIVERSITY AND ALLOW ECOSYSTEMS TO RECOVER. FURTHERMORE, CONTINUED RESEARCH AND MONITORING ARE ESSENTIAL TO BETTER UNDERSTAND THE COMPLEX INTERACTIONS WITHIN MARINE SYSTEMS AND TO INFORM EFFECTIVE CONSERVATION AND MANAGEMENT DECISIONS. THE URGENCY OF ADDRESSING CO₂ EMISSIONS AND THEIR OCEAN IMPACTS CANNOT BE OVERSTATED; THE HEALTH OF OUR PLANET AND THE FUTURE OF COUNTLESS SPECIES, INCLUDING OUR OWN, DEPEND ON IT.

FAQ

Q: HOW DOES INCREASED CO₂ IN THE ATMOSPHERE LEAD TO OCEAN ACIDIFICATION?

A: WHEN CARBON DIOXIDE (CO₂) FROM THE ATMOSPHERE DISSOLVES IN SEAWATER, IT REACTS WITH WATER TO FORM CARBONIC ACID. THIS CARBONIC ACID THEN DISSOCIATES, RELEASING HYDROGEN IONS. AN INCREASE IN HYDROGEN IONS LOWERS THE PH OF THE SEAWATER, MAKING IT MORE ACIDIC.

Q: WHAT ARE THE MAIN IMPACTS OF OCEAN ACIDIFICATION ON MARINE ORGANISMS?

A: OCEAN ACIDIFICATION PRIMARILY AFFECTS CALCIFYING ORGANISMS LIKE CORALS, SHELLFISH, AND PLANKTON, MAKING IT HARDER FOR THEM TO BUILD AND MAINTAIN THEIR SHELLS AND SKELETONS. IT CAN ALSO IMPAIR THE GROWTH, REPRODUCTION, AND SURVIVAL OF OTHER MARINE SPECIES, INCLUDING FISH.

Q: BESIDES ACIDIFICATION, WHAT OTHER MAJOR PROBLEM IS LINKED TO CO₂ EMISSIONS AND THE OCEAN?

A: ANOTHER SIGNIFICANT PROBLEM LINKED TO CO₂ EMISSIONS AND THE OCEAN IS DEOXYGENATION, WHICH IS THE LOSS OF DISSOLVED OXYGEN IN SEAWATER. THIS IS CAUSED BY WARMER WATERS HOLDING LESS OXYGEN AND INCREASED OCEAN STRATIFICATION, LEADING TO THE FORMATION OF "DEAD ZONES."

Q: HOW DO RISING SEA LEVELS AFFECT COASTAL COMMUNITIES AND ECOSYSTEMS?

A: RISING SEA LEVELS LEAD TO INCREASED COASTAL EROSION, MORE FREQUENT FLOODING, SALTWATER INTRUSION INTO FRESHWATER SOURCES, AND INUNDATION OF COASTAL HABITATS LIKE WETLANDS. THIS THREATENS INFRASTRUCTURE, HOMES, AGRICULTURE, AND VITAL ECOSYSTEMS, LEADING TO DISPLACEMENT AND ECONOMIC HARDSHIP.

Q: ARE ALL MARINE SPECIES EQUALLY AFFECTED BY OCEAN ACIDIFICATION?

A: NO, NOT ALL MARINE SPECIES ARE EQUALLY AFFECTED. CALCIFYING ORGANISMS ARE GENERALLY MORE VULNERABLE BECAUSE THEIR ABILITY TO FORM SHELLS AND SKELETONS IS DIRECTLY IMPACTED. HOWEVER, MANY NON-CALCIFYING ORGANISMS ALSO EXPERIENCE PHYSIOLOGICAL AND BEHAVIORAL CHANGES DUE TO ALTERED OCEAN CHEMISTRY.

Q: CAN CORAL REEFS RECOVER FROM THE IMPACTS OF CLIMATE CHANGE?

A: THE RECOVERY OF CORAL REEFS IS CHALLENGING DUE TO THE COMBINED PRESSURES OF WARMING OCEANS (CAUSING BLEACHING) AND OCEAN ACIDIFICATION. WHILE SOME RESILIENCE EXISTS, SUSTAINED HIGH LEVELS OF CO₂ EMISSIONS AND WARMING WILL SIGNIFICANTLY HINDER THEIR RECOVERY POTENTIAL.

Q: WHAT IS THE ROLE OF OCEAN DEOXYGENATION IN MARINE ECOSYSTEMS?

A: OCEAN DEOXYGENATION CREATES AREAS WITH INSUFFICIENT OXYGEN FOR MANY MARINE SPECIES TO SURVIVE. THIS CAN LEAD TO MASS DIE-OFFS, FORCE SPECIES MIGRATION, REDUCE BIODIVERSITY, AND DISRUPT FOOD WEBS, PARTICULARLY IMPACTING FISH STOCKS AND BENTHIC COMMUNITIES.

Q: WHAT ARE SOME PRACTICAL SOLUTIONS TO MITIGATE THE IMPACTS OF CO₂ EMISSIONS ON THE OCEAN?

A: KEY SOLUTIONS INCLUDE DRASTICALLY REDUCING GLOBAL CO₂ EMISSIONS BY TRANSITIONING TO RENEWABLE ENERGY, IMPROVING ENERGY EFFICIENCY, ADOPTING SUSTAINABLE LAND MANAGEMENT PRACTICES, AND IMPLEMENTING ADAPTATION

STRATEGIES LIKE PROTECTING AND RESTORING MARINE HABITATS AND ESTABLISHING MARINE PROTECTED AREAS.
